INTRODUCTION

Part I of this volume comprises a selection of original tables which have for the most part been reproduced directly from the computer print-out, but which had not been included in the first volume of the survey report. These tables consist of (a) the basic data on fertility and mortality which were used for the construction of the model fertility distributions and life tables for the domains of study (Vol. 1, pp. 79-80, 95-98): geographical Divisions and Hindus/Muslims; the tables for urban and rural domains have not been included, since it was found that the urban population had been seriously under-represented in the BRSFM sample; and (b) the data used for the analysis of differentials in infant and child mortality (Vol. 1, pp. 100-118). As with the national tables published in the first volume, certain discrepancies are apparent between the totals of the various tables both for the domains of study and for the differentials; the explanations for these discrepancies are the same as those given for the national tables on pages 22-23 of Volume 1. It should however be recalled that the tables are based on sample data which have been raised by ratio estimation to conform with the provisional census totals, by sex and Division, which were first released by the Government of Bangladesh after the 1974 census, and although these figures were later revised, it was then too late to amend the raising factors which had been incorporated in the computer processing of the survey. Thus the Divisional figures contained in this volume should add a total population for Bangladesh of approximately 71,316,500, although the revised total, as at 1st March 1974, was 76,398,000, (see Vol. 1, pp. 19-20).

Part II of this volume presents the results of an analysis of the sampling errors to which the survey results were subject. This analysis has been made by the World Fertility Survey using a computer package which they have specially developed for this purpose. Our thanks to the World Fertility Survey for their assistance in this matter is hereby gratefully acknowledged. This analysis constitutes the most thorough investigation which has yet been made of the sampling errors associated with the type of data used for the construction of the indirect estimates of fertility and mortality, and as such is of methodological interest beyond the confines of this particular survey. The sampling errors have in all cases been calculated for the various estimates by age group. It is not possible to present the sampling errors associated with the final estimates of the crude birth and death rates, as these were derived by indirect methods from a variety of sources and incorporated corrections for the non-sampling errors which in most cases were appreciably more serious than the sampling error.

PART II. SAMPLING ERRORS

Description 183-188

Table

1. Average parity 189
2. Proportion of male children dying 190

3. Proportion of female children dying 191
4. Current age-specific fertility rates 192
5. Proportion of males with father alive 193
6. Proportion of females with father alive 194
7. Proportion of males with mother alive 195
8. Proportion of females with mother alive 196
9. Proportion of eldest surviving sons with father alive 197
10. Proportion of eldest surviving daughters with father alive 198
11. Proportion of eldest surviving sons with mother alive 199
12. Proportion of eldest surviving daughters with mother alive 200
13. Proportion of males ever married 201
14. Proportion of females ever married 202
15. Proportion of ever-married males with first wife alive 203
16. Proportion of ever-married females with first husband alive 204
17. Proportion of living males above specified ages 205
18. Proportion of living females above specified ages 206
19. Proportion of males dying in 12 months before the survey above specified ages 207
20. Proportion of females dying in 12 months before the survey above specified ages 208
21. Proportion of males dying in 12-24 months before the survey above specified ages 209
22. Proportion of females dying in 12-24 months before the survey above specified ages 210

PART I - TABLES

Tables for Divisions and for Muslims/Hindus

The tables[1] included in this section for each Division, for Muslims and for Hindus are:

Table 3: Population by sex, 5-year age groups, marital status and number of marriages (once only; more than once; not stated).

Table 4: Ever-married population by sex, 5-year age groups, and survival of first spouse (wife/husband alive; wife/husband dead; wife/husband not stated).

Table 5: Population by sex, 5-year age groups, survival of father (father alive; father dead; father not stated) and sibship status (eldest surviving children of the father only; younger surviving children; not stated).

Table 6: Population by sex, 5-year age groups, survival of mother (mother alive; mother dead; mother not stated) and sibship status (eldest surviving children of the mother only; younger surviving children; not stated).

Table 8: Ever-married women by 5-year age groups, with total children ever borne, number at home, number elsewhere and number dead by sex of children.

Table 9: Ever-married women by 5-year age groups and number of children ever borne (0, 1 ... 9, 10+, not stated).

Table 10: Ever-married women by 5-year age groups, date of last birth April 73 - March 74; April 72 - March 73; before April 72; 1973 month not stated; 1972 month not stated; no date stated), and survival of the child (alive; dead; not stated).

Table 11: Ever-married women bearing children in the last 24 months (i.e. since April 1972) by 5-year age groups and month of the birth.

Table 12: Ever-married women bearing children in the last 12 months (i.e. since April 1973) by 5-year age groups and number of children ever borne (1, 2 ... 9, 10+, not stated).

Table 13: Ever-married women "not stated" as to date of last birth by 5-year age groups and number of children ever borne (1, 2 ... 9, 10+, not stated).

Table 14: Ever-married women bearing children in the last 12 months by 5-year age groups and 5-year age group of husband.

---

1. Table numbers refer to those of the original tabulation programme (see Vol. I, pp. 153-155).

Table 15: Members of the household dying during the last 24 months (i.e. since April 1972) by age (0, 1, 2, 3, 4, 5-9, 10-14 ... 70-74, 75+, not stated) and year and month. This table has been presented for Divisions only. It could not be run for Muslims and Hindus as the religion of the deceased persons was not recorded on the survey schedules.

Tables for Differentials in Fertility and Child Mortality

The tables in this section consist of the cross-tabulations of Table 8 (Ever-married women by 5-year age groups, with total children ever borne, number at home, number elsewhere and number dead by sex of children) and Table 9 (Ever-married women by 5-year age groups and number of children ever borne) against the following socio-economic and geographical characteristics:

(i) Education of the woman (None; Grades 1 - 5; Grades 6 and over). The sum of the figures in these three tables will not equal those of the Tables 8 and 9 for all ever-married women published in Volume I due to the exclusion of women who were shown as having attended school but who were "not stated" as to grade or whose grade was shown as 0.

(ii) For Hindus only: Caste (Caste Hindus/Scheduled Castes).

(iii) Marital Status (Married; widowed; divorced) and number of marriages (once only/more than once). Tables for the small numbers of women who were "not stated" as to either marital status or number of marriages have been omitted.

(iv) Education of the husband (Grades 1 - 5; Grades 6 and over). The table for husbands with no education has been omitted, as, due to an error in the specifications this table also included widowed and divorced women and other women whose husbands' particulars were not recorded on the same schedule.

(v) Husband present last night (Husband present; husband absent; husband not stated). These tables should be interpreted with caution as, again due to an error in the specifications, some widowed and divorced women have been included in the categories "Husband absent" and "Husband not stated".

(vi) Type of house (Type 1: walls of burnt bricks, concrete or stone and roof of tiles or cement; Type 2: walls of burnt bricks, concrete or stone and roof of corrugated iron; Type 3: walls of mud, unburnt bricks or corrugated iron and roofs of corrugated iron; Type 4: walls of mud or unburnt bricks and roofs of thatch or reed).

(vii) Administrative District. These tables show summary figures by age group of the main features of Tables 8 and 9 only: total women; total births; children dead; childless women. The original computer tabulations had been run for the 66 Census Districts, but it was found that the sample sizes at this level were too small to permit meaningful analyses, so the most crucial figures were summarised by hand to provide data for the 19 Administrative Districts as shown here.

(viii) Rural and urban. Although it was originally intended to treat the urban and rural population as domains of study, it was found that the urban population was, for reasons unknown, badly under-represented in the sample. The full set of tables have therefore been omitted from this volume. Tables 8 and 9, however, which show the differentials discussed on pages 67, 70, 81, 84, 112 and 114 of Volume I have been included in this section.

PART II - ANALYSIS OF SAMPLING ERRORS

The tables included in this section show the results of the analysis of the sampling errors which has been made using the World Fertility Survey's package computer programme CLUSTERS[1]. Persons requiring further details of the formulae used and the methods of computation should refer to the WFS Users' Manual for CLUSTERS: A Package Programme for Computation of Sampling Errors for Clustered Samples[2].

The tables published here show the sampling errors at national level only. Similar analyses, however, have been made for each of the four Divisions, but considerations of space, etc., have precluded their publication in this volume. In general the standard errors of the estimates at Division level were approximately twice as great as those at national level. This result is of course in accordance with expectation since the standard errors tend to vary inversely with the square root of the size of the sample.

Each of the 22 tables shows the sampling errors and associated quantities, by age group, for a particular ratio or proportion which was used for the construction of the indirect estimates of fertility and/or mortality. Each table contains the following quantities:

(i) The estimated ratio or proportion for which the sampling errors have been calculated. These estimates unfortunately differ slightly from the corresponding figures already published in the first volume of the survey report,

---

1. Computation and Listing of Useful STatistics on ERrors of Sampling.
2. Published by the World Fertility Survey, 35-37 Grosvenor Gardens, London, SW1W 0BS, United Kingdom, April 1977.

due to some re-editing of the magnetic tape which was found necessary before the data could be run with the CLUSTERS programme.

(ii) The standard error of the estimate, computed in accordance with the formulae set out in the WFS Users' Manual.

(iii) The relative standard error - i.e. $\frac{\text{Standard Error}}{\text{Estimate}}$

(iv) The lower and upper limits of the 95% confidence interval of the estimate - i.e. Estimate $\pm$ 1.96 x Standard Error.

(v) The random error - i.e. the standard error which would have been expected had the sample been a purely random one of individuals or households. Again the formula used for the computation of this quantity may be found in the WFS Users' Manual.

(vi) The design effect, or the ratio $\frac{\text{Standard Error}}{\text{Random Error}}$, which thus measures the relative increase in the standard error which has resulted from the use of a cluster sample rather than a purely random sample. It may be observed that with an average cluster size of about 750 persons, the value of the design effect for most of the more crucial estimates lay between 1.5 and 2.0. But it should also be noted that these figures comprise an element of "interviewer effect": for example, if certain clusters had been enumerated by poor interviewers who had introduced consistent biases into the data for their areas, the variances of the characteristics so affected will have been artificially increased. In this respect the sampling errors and non-sampling errors cannot here be wholly divorced.

(vii) The number, N, of relevant persons (males, females, eldest surviving males/females, ever-married males/females) in the total sample. These numbers vary slightly from table to table, due to the exclusion of small numbers of cases with "exceptional values" - persons whose data in respect of the variable under consideration were regarded as being in some way defective.

(viii) The average number of relevant persons per cluster - i.e. N/482, since there were 482 sample areas covered by the survey.

Table 1: Average Parity, or the mean number of children ever born per woman. This ratio is of crucial importance for the estimation of fertility, particularly the values for the younger women in the age groups 15-19, 20-24 and 25-29 which determined both the level and shape of the age-specific fertility model (Vol. I pp. 160-163). The standard errors of these estimates were comfortably low, the relative standard errors being little more than 1%, except in the case of the 15-19 age group where, due to sensitivity to variations in age at marriage, it was of the order of 3%. The design effect for this characteristic, however, was rather higher than those calculated for some of the other variables, and reached a figure of nearly 2.5 for the 25-29 age group.

Table 2 and 3: Proportions of Male and Female Children Dying. These proportions form the cornerstone of the estimates of infant and child mortality (Vol. I pp. 164-5), particularly the values for the 20-24, 25-29 and 30-34 age groups of mothers. The relative standard errors lay between 2 and 3%.

Table 4: Current Age-Specific Fertility Rates - i.e. the proportion of women in each age group whose most recent birth was reported as having occurred during the 12 months preceding the survey. These rates were also used for determining the shape of the age-specific fertility model, and for estimating the mean ages of fathers and mothers at the birth of their children which were important parameters for the estimation of adult mortality from data on orphanhood. For women in their 20's and 30's, where the current fertility rates were high, the relative standard errors lay between 2½ and 3½ per cent,

but at the tails of the distribution where the numbers of current births were small, the sampling errors were appreciably larger, resulting in uncomfortably wide confidence intervals. This fact, combined with the vulnerability of these rates to the effects of age mis-reporting, stresses the danger of attributing too much weight to the fertility rates of women under 20 or over 40 when estimating basic demographic parameters.

Tables 5 - 8: Proportions of Males and Females with Father and with Mother Alive. These data were used for the estimation of adult mortality, with primary reliance on the reports of females between the ages of 15 and 45 (Vol. I, pp. 84-87, 166-168). The sampling errors for these characteristics were low, but the relative standard errors tended to increase with age as the numbers decreased, being under 1% for females 15-19 and 20-24 but reaching 2.1% for women aged 40-44 with mothers alive and 4.3% for those with fathers alive. The design effects of the data on fathers were generally rather higher than those of the data on mothers.

Table 9 - 12: Proportions of Eldest Surviving Sons and Daughters with Father and with Mother Alive. These data were also used for the estimation of adult mortality rates, and the standard errors, though marginally higher than those based on all respondents, were still low.

Table 13 - 14: Proportions of Males and of Females Ever Married. These data formed the basis of the analysis of changes in age at marriage, and the mean age at first marriage so derived was also an important parameter for the conversion of the data on widowhood into adult mortality rates (Vol. I, pp. 56-58, 167-168). In this

respect the crucial age groups were 15-19 for females, and 20-24 for males. Although the standard errors of the proportions ever-married at these ages were not large in absolute terms, they were appreciably greater than would have been expected on the basis of a random sample, so that the design effect reached values of over 3.

Tables 15 - 16: Proportions of Ever-Married Males and Females with First Wife/Husband Alive. The proportions were also used to provide estimates of adult mortality, the data used being those of respondents between the ages of 25 and 65 (Vol. I, pp. 84-87, 167-168). Standard errors were again low, being similar in magnitude to those of the orphanhood data.

Tables 17 - 18: Proportions of Living Males and of Living Females Above Specified Ages. These proportions formed the denominators of the ratios N_y/P_y and D_y/P_y of the "death distribution" technique of mortality estimation (Vol. I, pp. 170-173). It should also be observed that the complements of these proportions - i.e. the proportions under the specified ages - were used for the estimation of fertility by comparison with stable population models (Vol. I, pp. 75-76). The standard errors of the complements would normally be identical with those of the proportions shown. At all ages and for both sexes the standard errors were negligible in comparison with the non-sampling errors in the age distribution due to age mis-reporting.

Tables 19 - 22: Proportions of Males and Females Dying in the 12 Months Before the Survey and in the 12 - 24 Months before the Survey, Above Specified Ages. These proportions constituted the numerators of the D_y/P_y ratios of the death distribution method. In this case the sampling errors were by no means negligible. Although the

absolute values of the standard errors tended to fall with age, the relative standard errors increased, reaching values of over 6% at ages over 40. This fact should be borne in mind in view of the fact that the points at older ages exercise a large moment in the fitting of the straight line, whatever method of fitting is adopted. An interesting feature of these tables is the relatively low values of the design effects.
